Chapter 2: Fourier Analysis of Signals

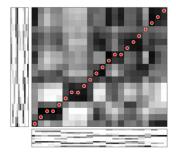

- 2.1 The Fourier Transform in a Nutshell
- 2.2 Signals and Signal Spaces
- 2.3 Fourier Transform
- 2.4 Discrete Fourier Transform (DFT)
- 2.5 Short-Time Fourier Transform (STFT)
- 2.6 Further Notes

Important technical terminology is covered in Chapter 2. In particular, we approach the Fourier transform—which is perhaps the most fundamental tool in signal processing—from various perspectives. For the reader who is more interested in the musical aspects of the book, Section 2.1 provides a summary of the most important facts on the Fourier transform. In particular, the notion of a spectrogram, which yields a time–frequency representation of an audio signal, is introduced. The remainder of the chapter treats the Fourier transform in greater mathematical depth and also includes the fast Fourier transform (FFT)—an algorithm of great beauty and high practical relevance.

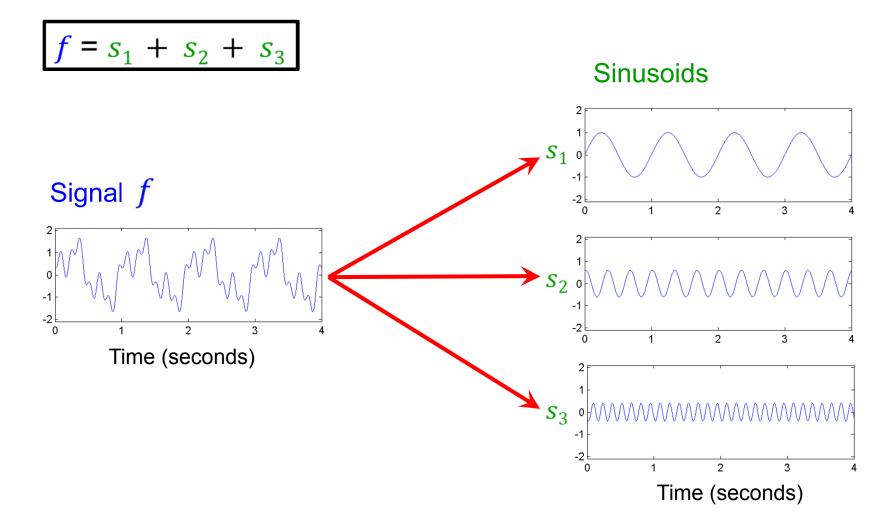

Chapter 3: Music Synchronization

- 3.1 Audio Features
- 3.2 Dynamic Time Warping
- 3.3 Applications
- 3.4 Further Notes

As a first music processing task, we study in Chapter 3 the problem of music synchronization. The objective is to temporally align compatible representations of the same piece of music. Considering this scenario, we explain the need for musically informed audio features. In particular, we introduce the concept of chroma-based music features, which capture properties that are related to harmony and melody. Furthermore, we study an alignment technique known as dynamic time warping (DTW), a concept that is applicable for the analysis of general time series. For its efficient computation, we discuss an algorithm based on dynamic programming—a widely used method for solving a complex problem by breaking it down into a collection of simpler subproblems.

Idea: Decompose a given signal into a superposition of sinusoids (elementary signals).

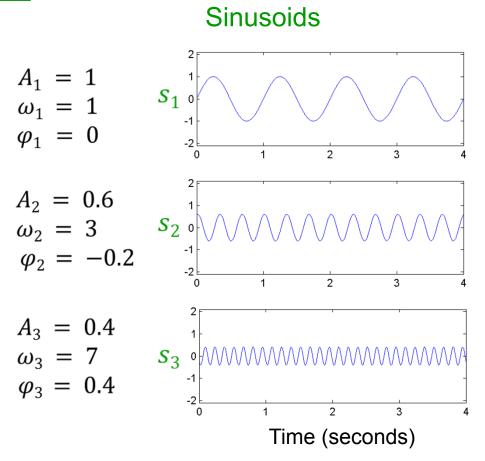

Each sinusoid has a physical meaning and can be described by three parameters:

 $s_{(A, \omega, \varphi)}(t) = A \cdot \sin(2\pi(\omega t - \varphi))$

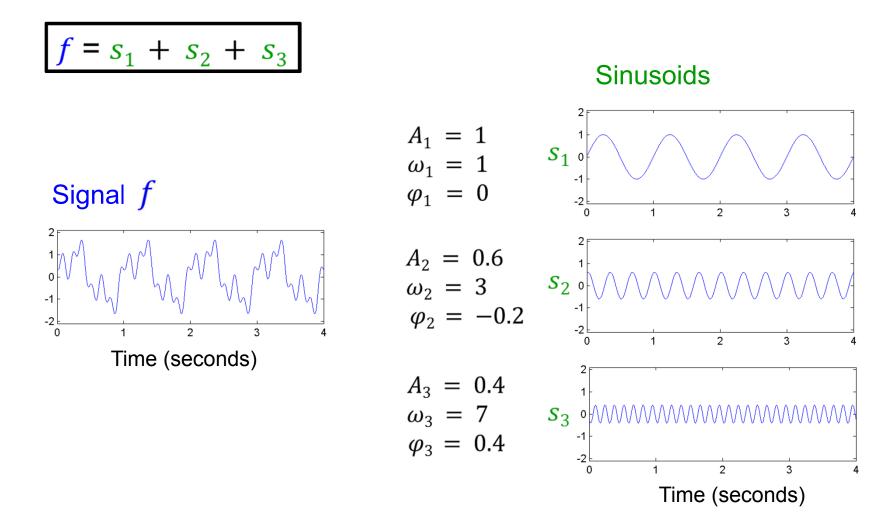

$$\omega =$$
frequency
 $A =$ amplitue
 $\varphi =$ phase

Interpretation:

The amplitude *A* reflects the intensity at which the sinusoidal of frequency ω appears in *f*. The phase φ reflects how the sinusoidal has to be shifted to best correlate with *f*.

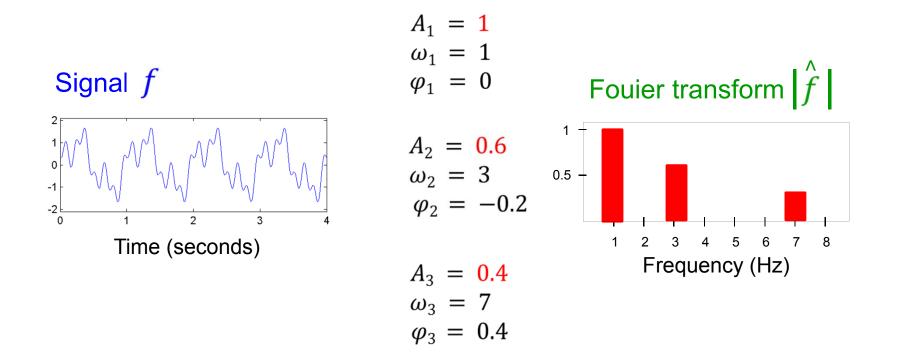

Each sinusoid has a physical meaning and can be described by three parameters:

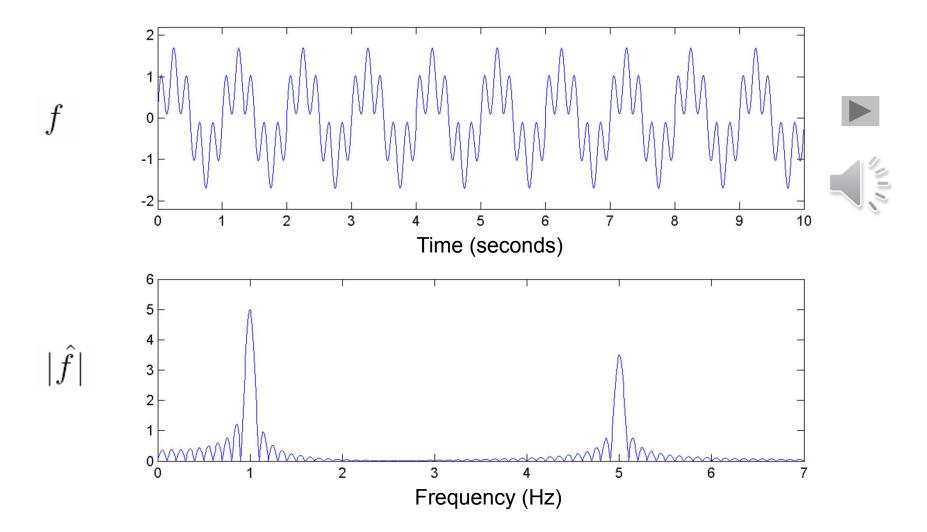

Each sinusoid has a physical meaning and can be described by three parameters:

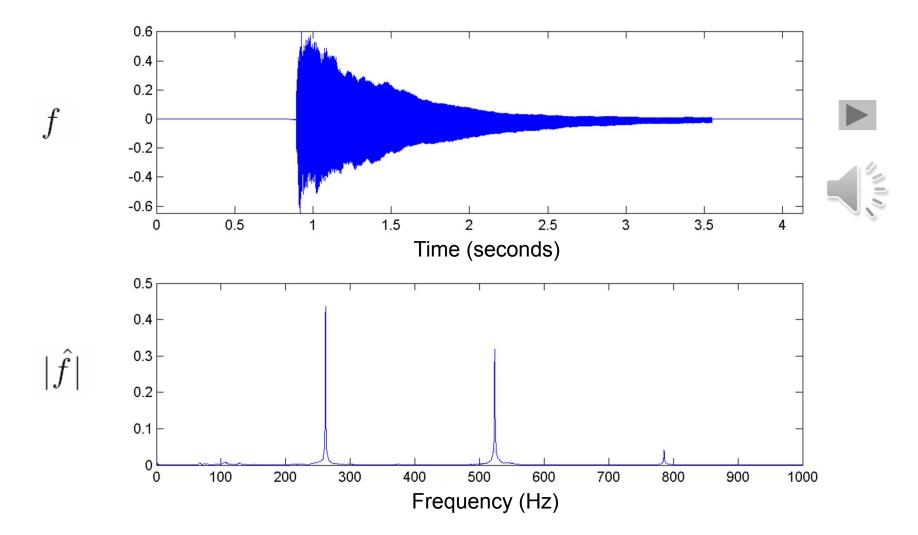

$$f = s_1 + s_2 + s_3$$

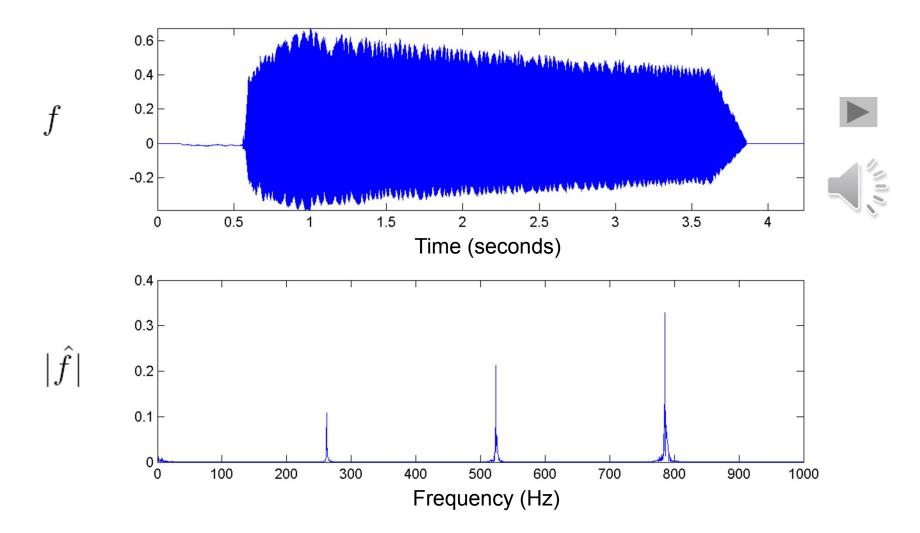

Example: Superposition of two sinusoids

Fourier Transform Role of phase

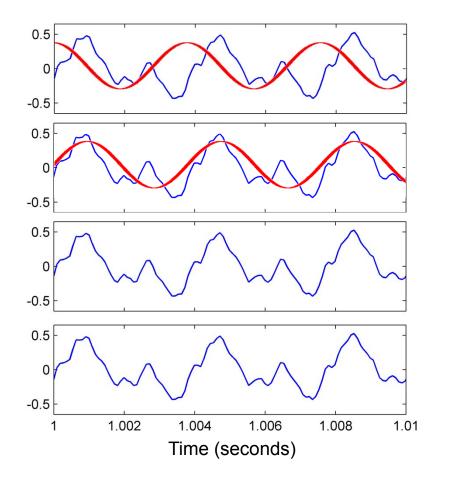

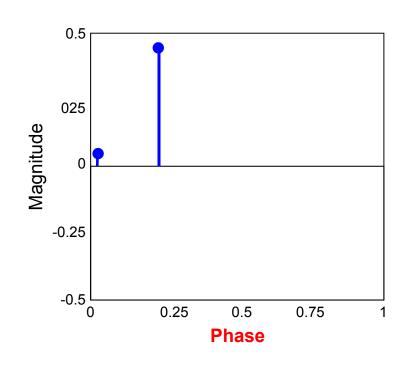

Role of phase

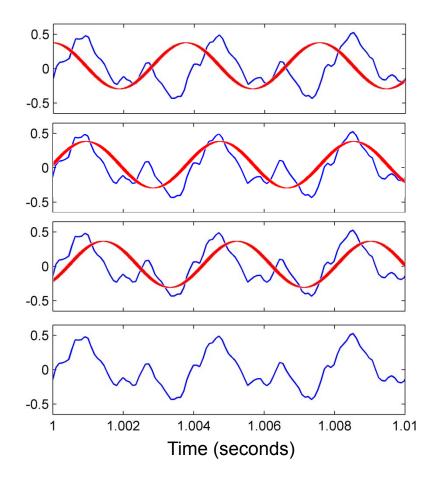

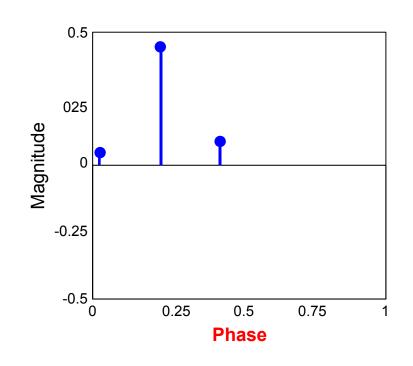

Role of phase

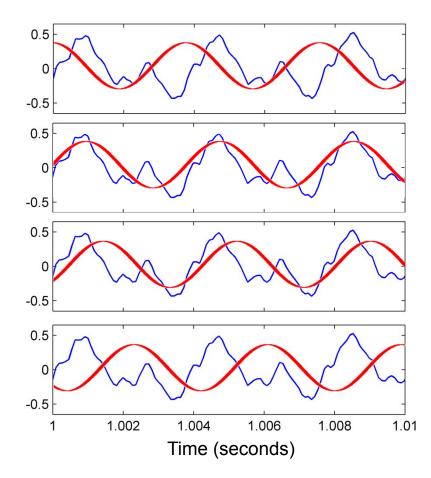

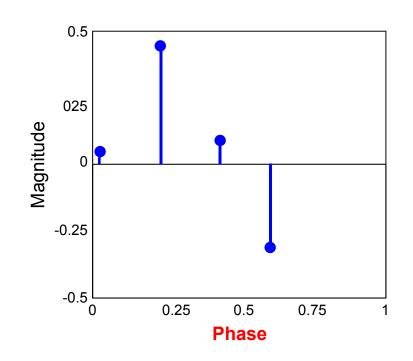

Role of phase

Role of phase

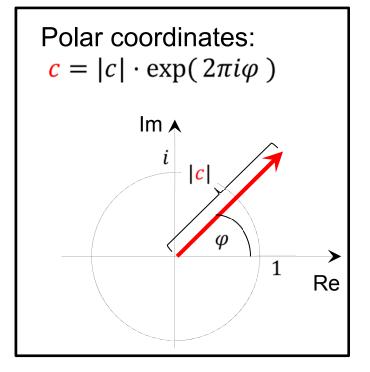

Each sinusoid has a physical meaning and can be described by three parameters:

$$s_{(A, \omega, \varphi)}(t) = A \cdot \sin(2\pi(\omega t - \varphi))$$

$$\omega =$$
frequency
 $A =$ amplitue
 $\varphi =$ phase

Complex formulation of sinusoids:

 $e_{(C,\omega)}(t) = \mathbf{c} \cdot \exp(2\pi i\omega t) = \mathbf{c} \cdot (\cos(2\pi\omega t) + i \cdot \sin(2\pi\omega t))$

$$\omega = frequency$$

$$A = \text{amplitue} = |c|$$

 $\varphi = \text{phase} = \arg(c)$

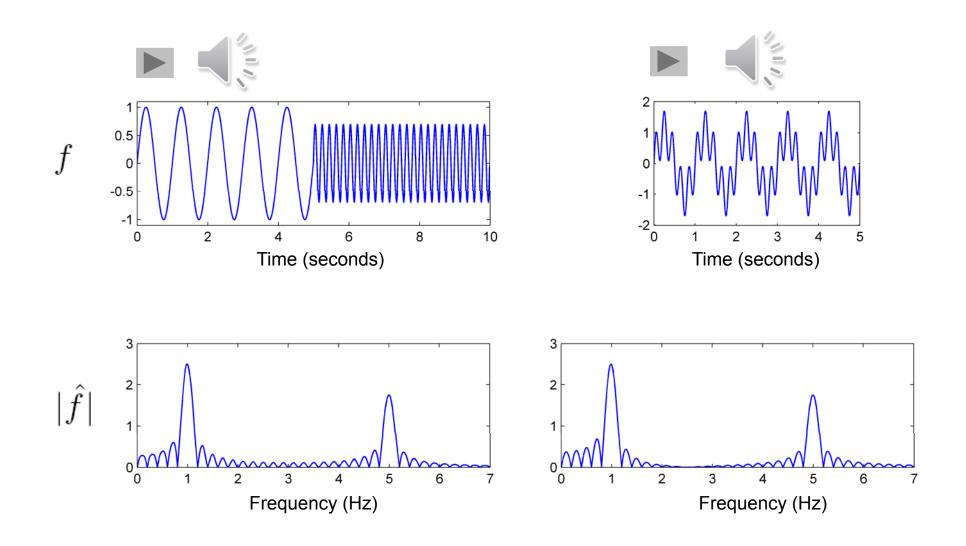

Signal $f: \mathbb{R} \to \mathbb{R}$ Fourier representation $f(t) = \int_{\omega \in \mathbb{R}} c_{\omega} \exp(2\pi i \omega t) d\omega$

Fourier transform $c_{\omega} = \hat{f}(\omega) = \int_{t \in \mathbb{R}} f(t) \exp(-2\pi i \omega t) dt$

- Signal $f: \mathbb{R} \to \mathbb{R}$
- Fourier representation $f(t) = \int_{\omega \in \mathbb{R}} c_{\omega} \exp(2\pi i \omega t) d\omega$

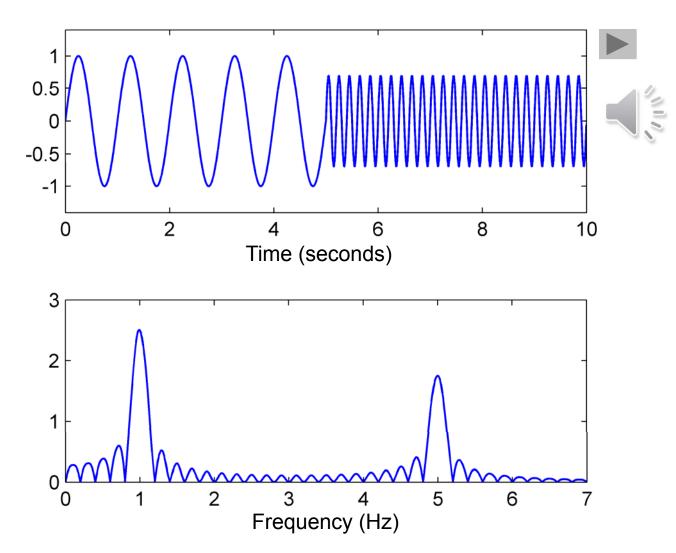

Fourier transform
$$c_{\omega} = \hat{f}(\omega) = \int_{t \in \mathbb{R}} f(t) \exp(-2\pi i \omega t) dt$$

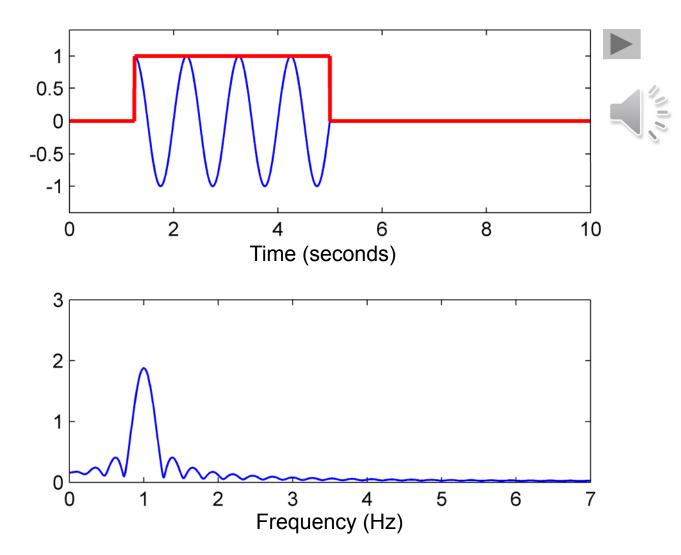

- Tells which frequencies occur, but does not tell when the frequencies occur.
- Frequency information is averaged over the entire time interval.
- Time information is hidden in the phase

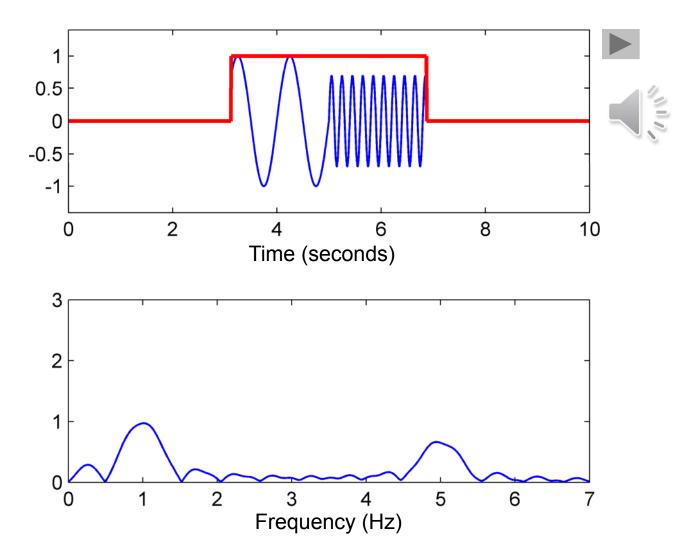

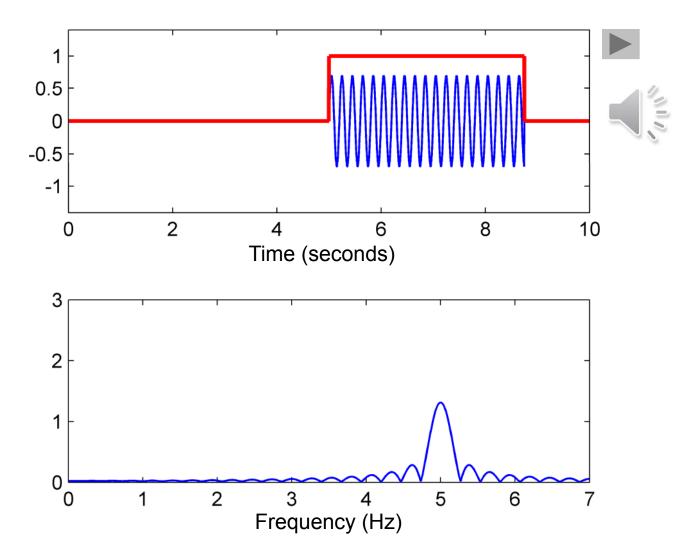

Idea (Dennis Gabor, 1946):

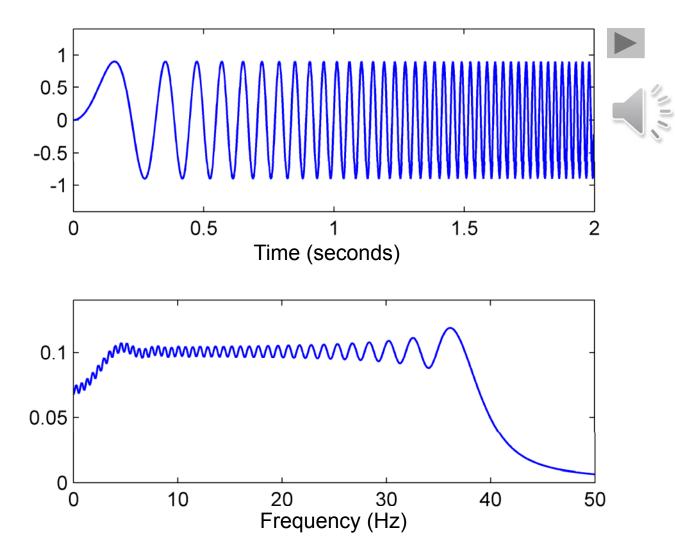

- Consider only a small section of the signal for the spectral analysis
 - \rightarrow recovery of time information
- Short Time Fourier Transform (STFT)
- Section is determined by pointwise multiplication of the signal with a localizing window function

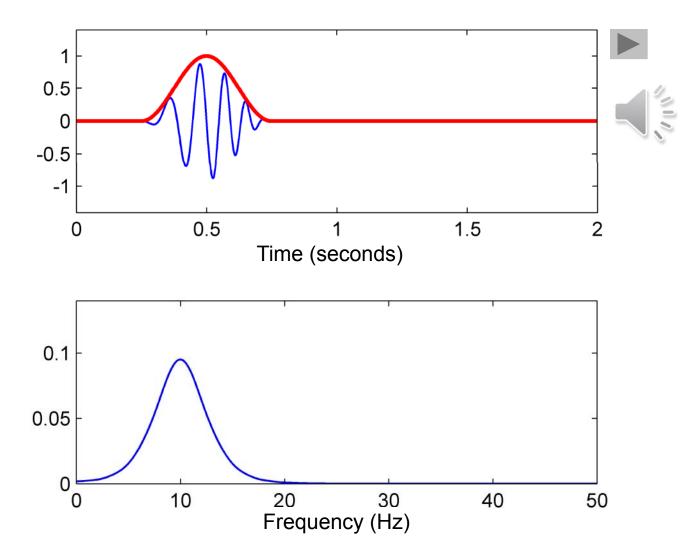

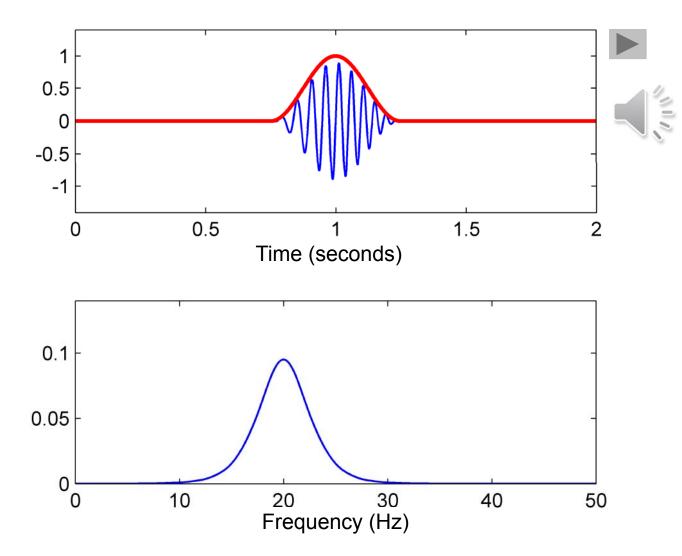

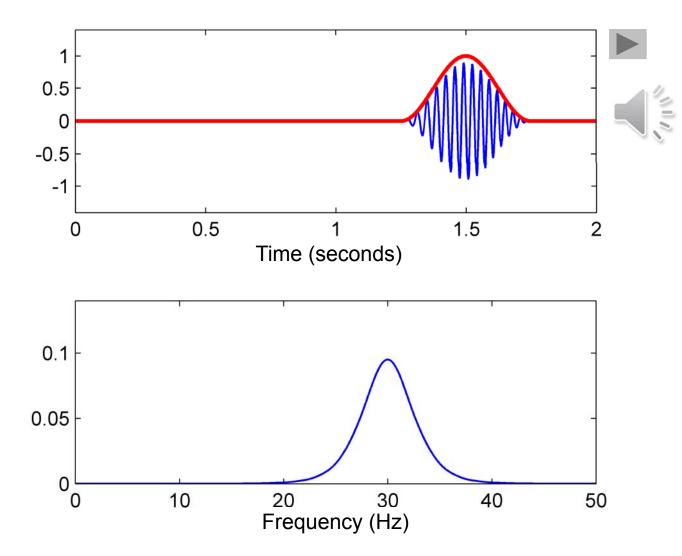

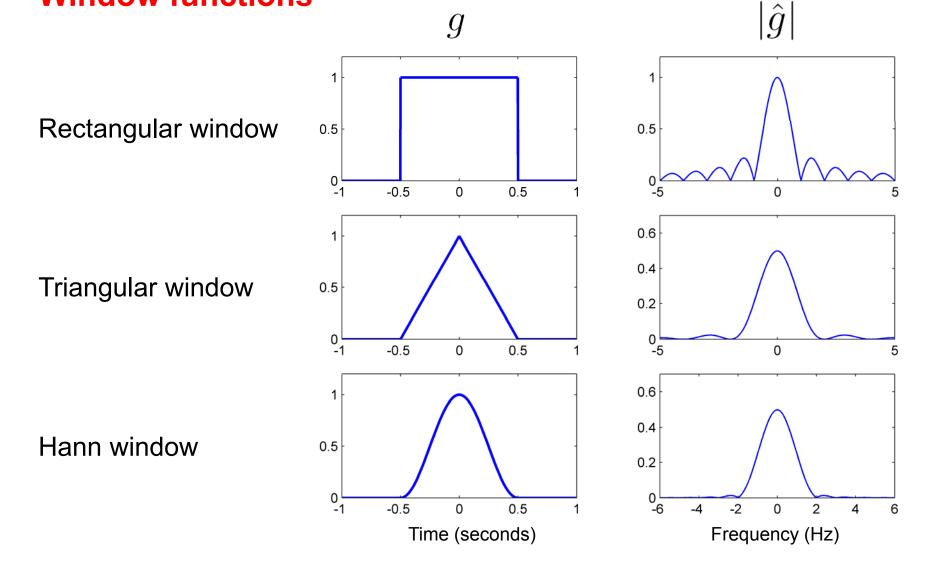

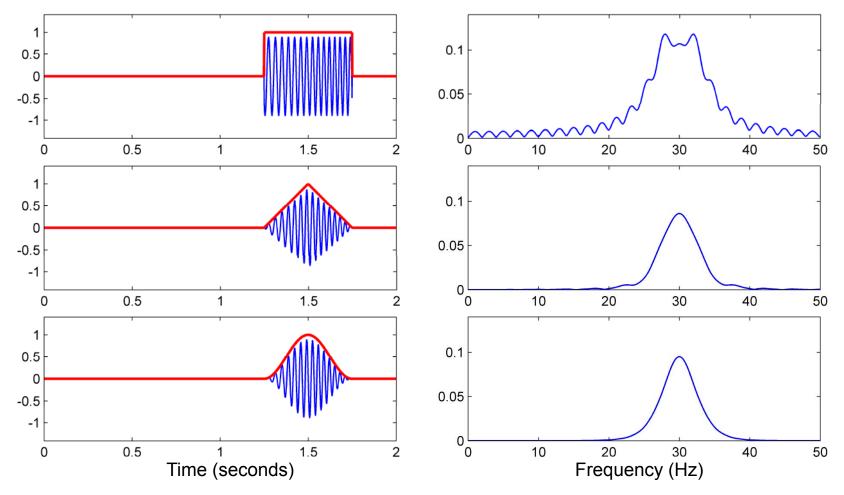

Short Time Fourier Transform Window functions

Window functions

 \rightarrow Trade off between smoothing and "ringing"

Definition

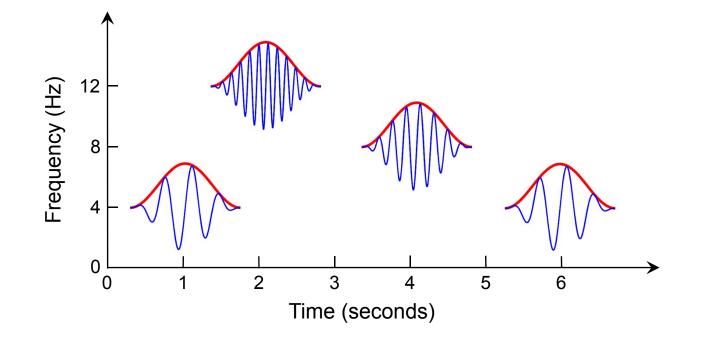

- Signal $f: \mathbb{R} \to \mathbb{R}$
- Window function $g:\mathbb{R}\to\mathbb{R}$ ($g\in L^2(\mathbb{R}), \|g\|_2
 eq 0$)

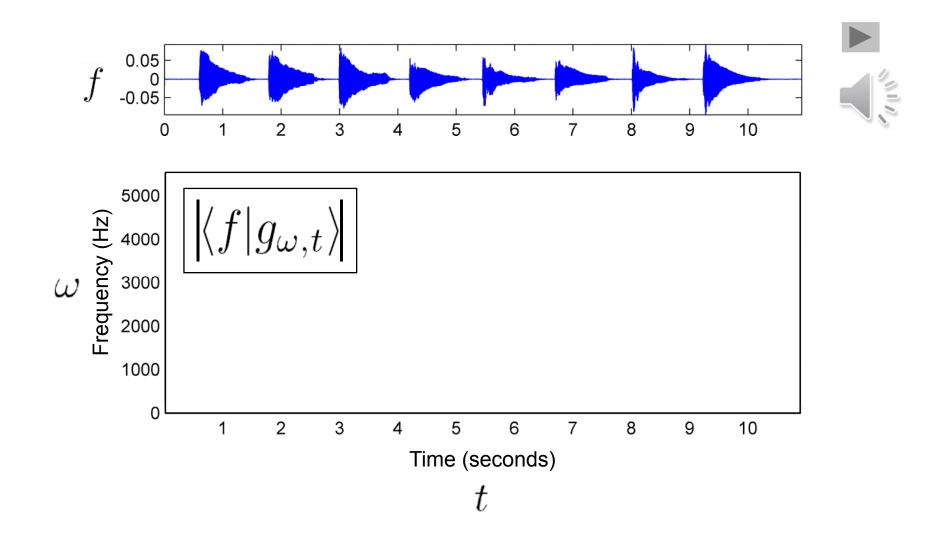

• STFT
$$\tilde{f}_g(t, \omega) = \int_{u \in \mathbb{R}} f(u)\overline{g}(u-t) \exp(-2\pi i\omega u) du = \langle f|g_{t,\omega} \rangle$$

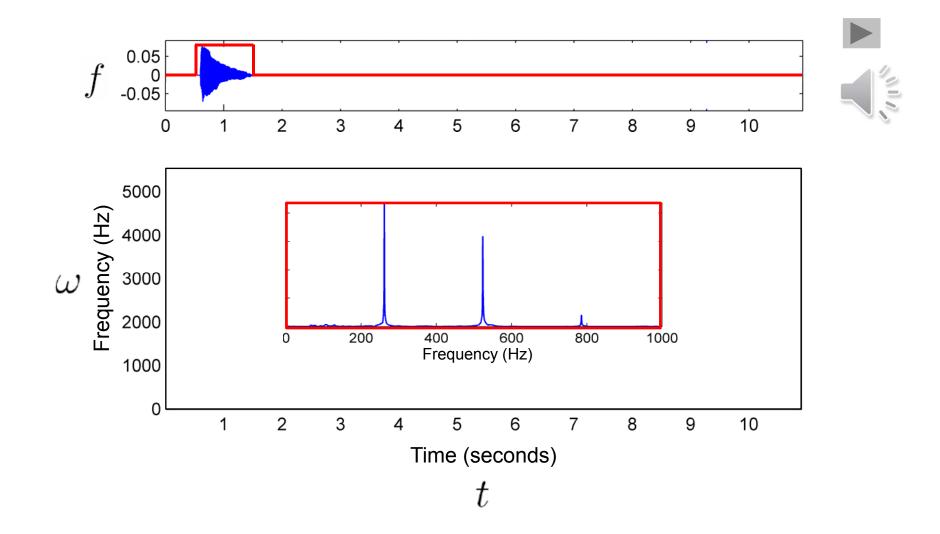

with
$$g_{t,\omega}(u) = \exp(2\pi i\omega(u-t))g(u-t)$$
 for $u \in \mathbb{R}$

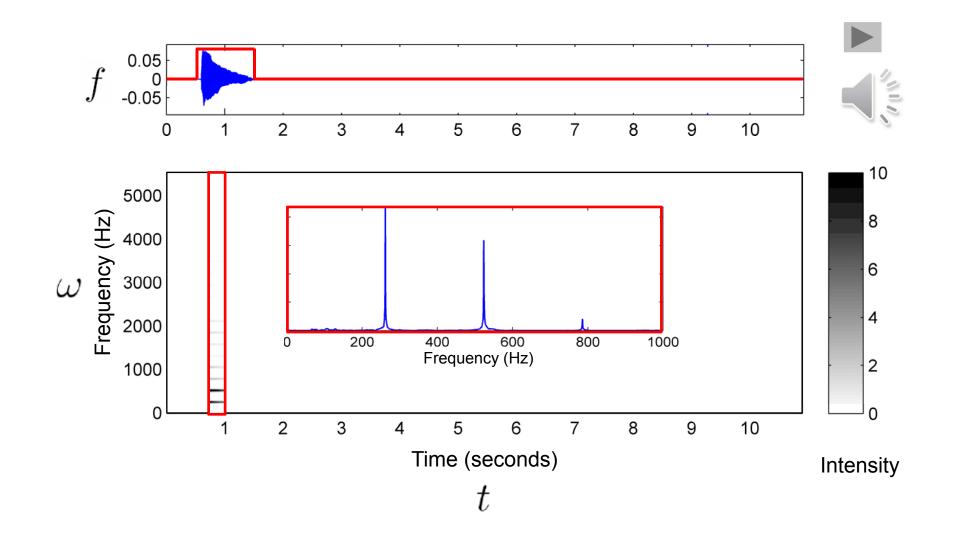

Intuition:

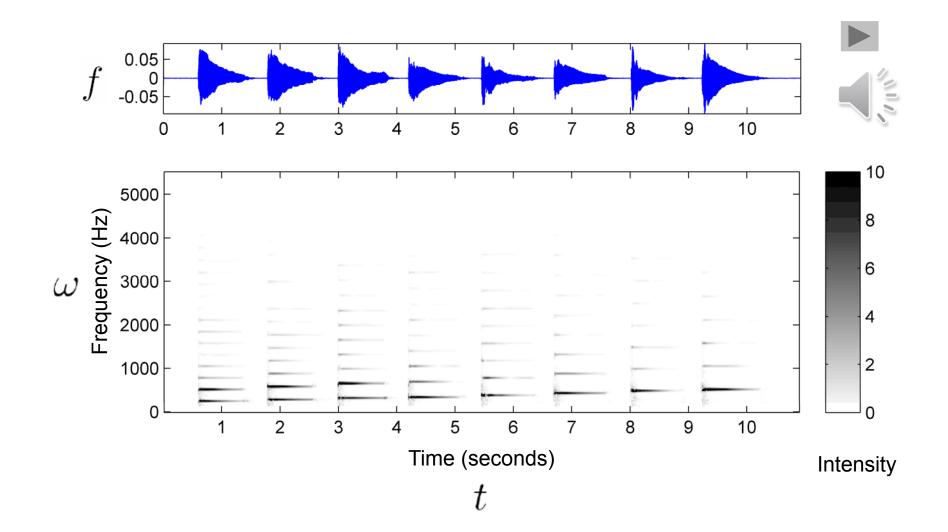

- $g_{t,\omega}$ is "musical note" of frequency ω centered at time t
- Inner product $\langle f|g_{t,\omega}\rangle$ measures the correlation between the musical note $g_{t,\omega}$ and the signal f

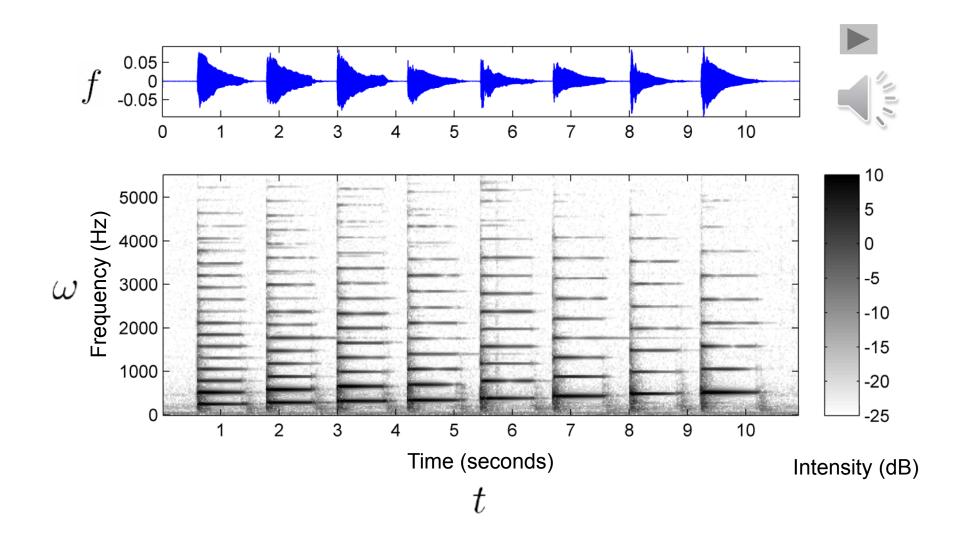

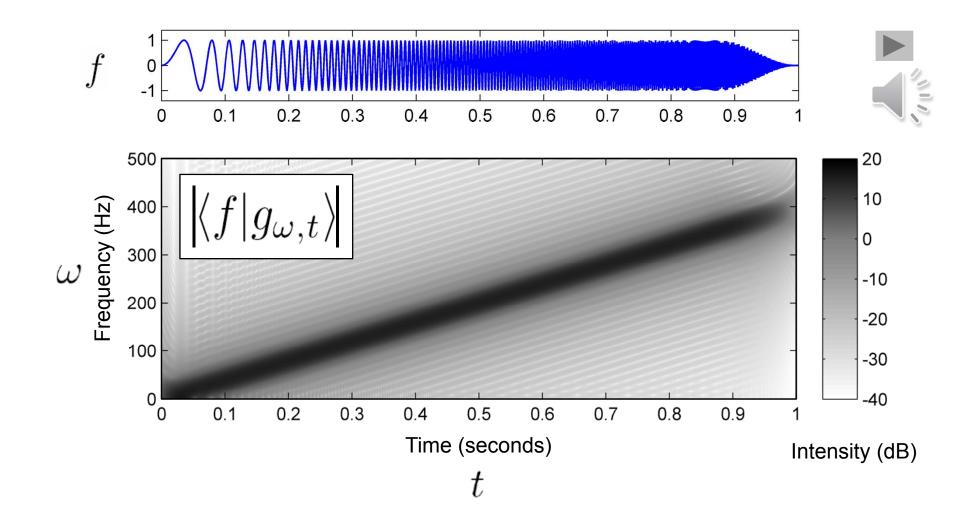

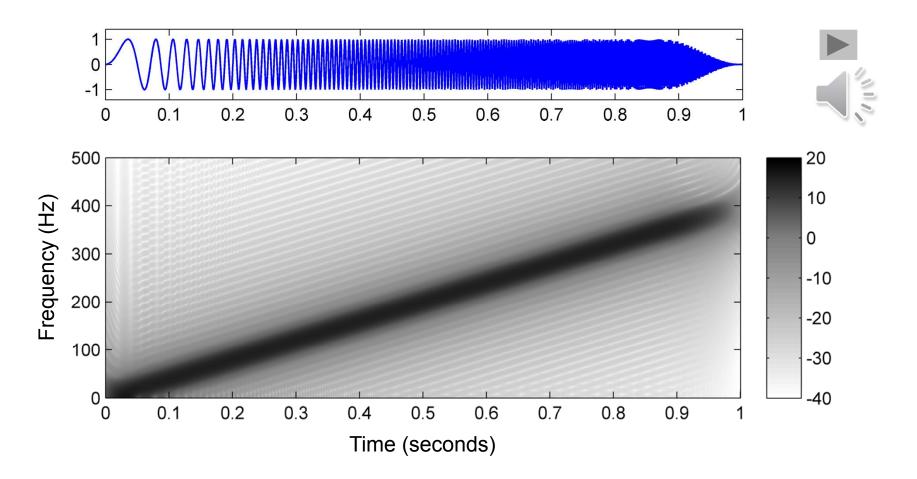

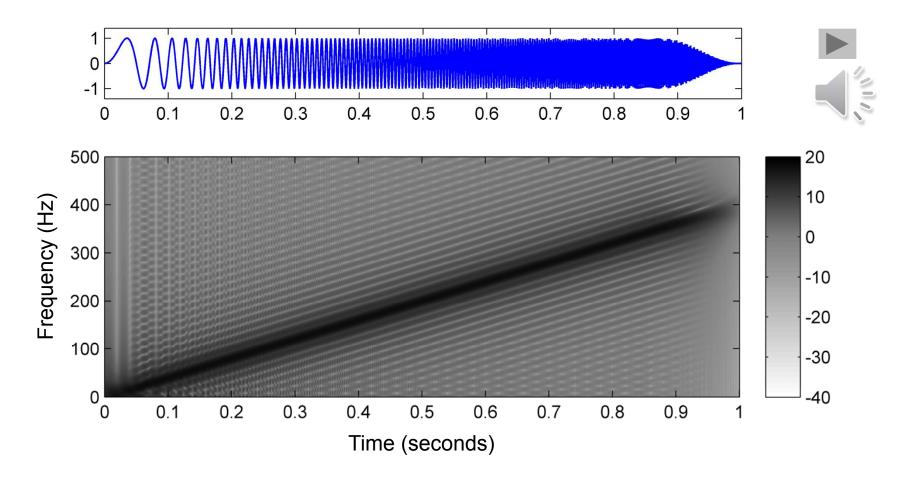

Time-Frequency Representation

Chirp signal and STFT with Hann window of length 50 ms

Time-Frequency Representation

Chirp signal and STFT with box window of length 50 ms

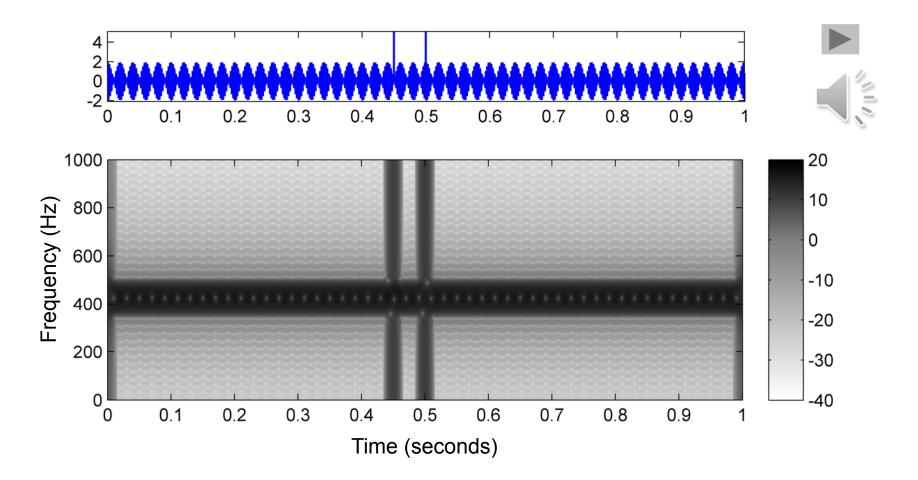

Time-Frequency Representation Time-Frequency Localization

- Size of window constitutes a trade-off between time resolution and frequency resolution:
 - Large window : poor time resolution good frequency resolution Small window : good time resolution poor frequency resolution
- Heisenberg Uncertainty Principle: there is no window function that localizes in time and frequency with arbitrary precision.

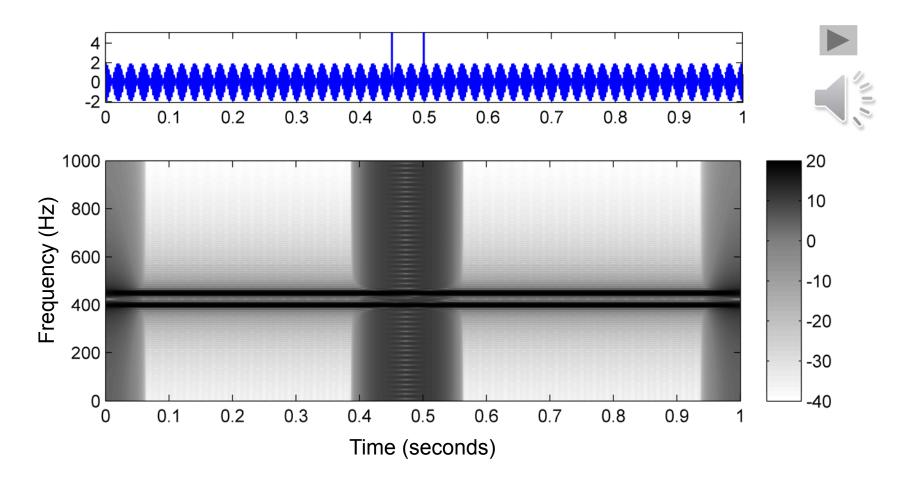

Time-Frequency Representation

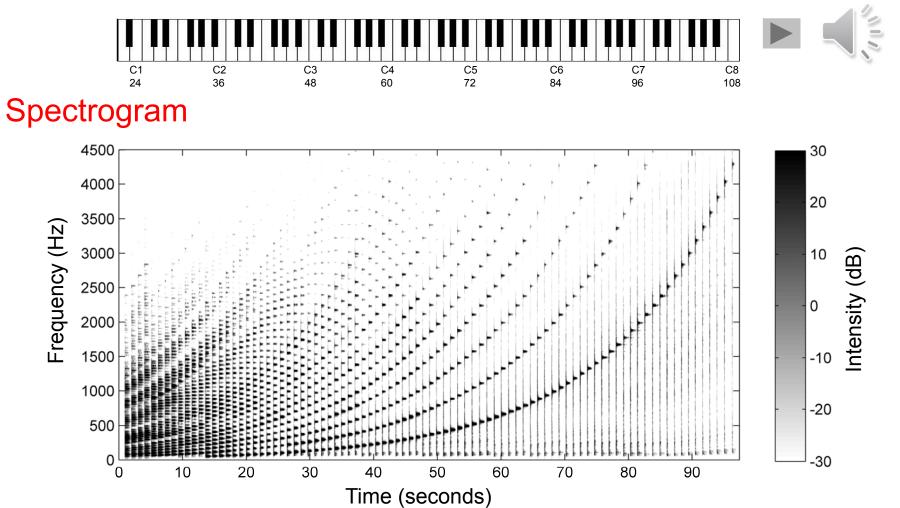

Signal and STFT with Hann window of length 20 ms

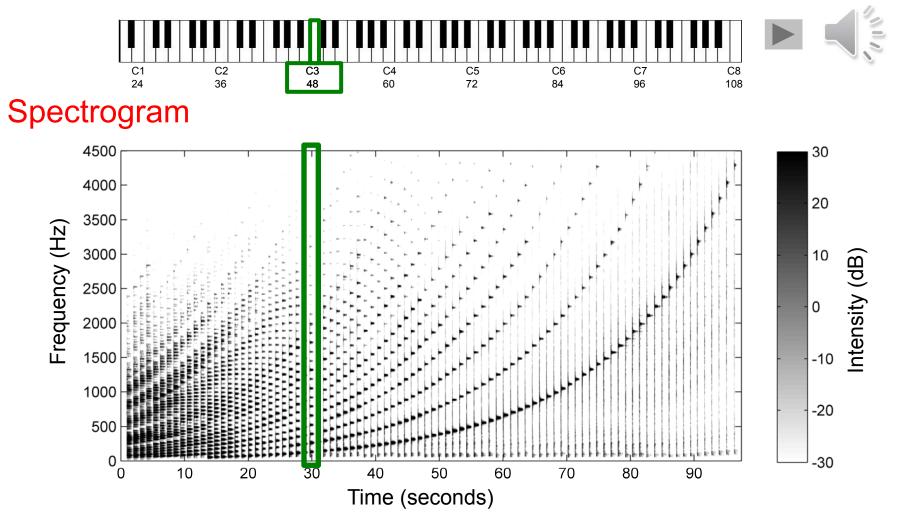

Time-Frequency Representation

Signal and STFT with Hann window of length 100 ms

Model assumption: Equal-tempered scale

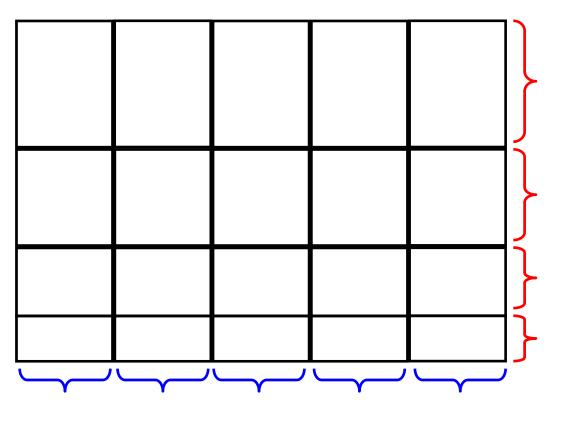

- MIDI pitches: $p \in [1:128]$
- Piano notes: p = 21 (A0) to p = 108 (C8)
- Concert pitch: $p = 69 (A4) \triangleq 440 \text{ Hz}$
- Center frequency: $F_{\text{pitch}}(p) = 2^{(p-69)/12} \cdot 440 \text{ Hz}$

→ Logarithmic frequency distribution Octave: doubling of frequency

Idea: Binning of Fourier coefficients

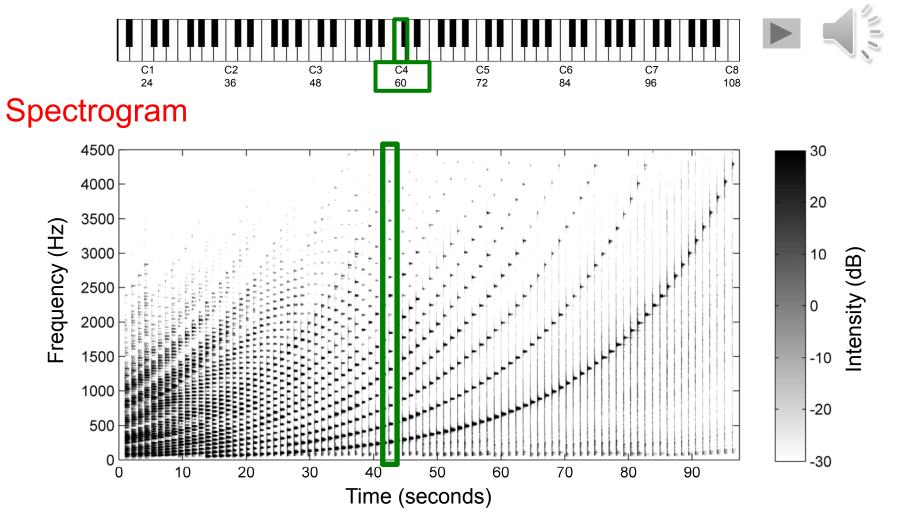

Divide up the fequency axis into logarithmically spaced "pitch regions" and combine spectral coefficients of each region to a single pitch coefficient.

Chroma features

Chromatic circle

Shepard's helix of pitch

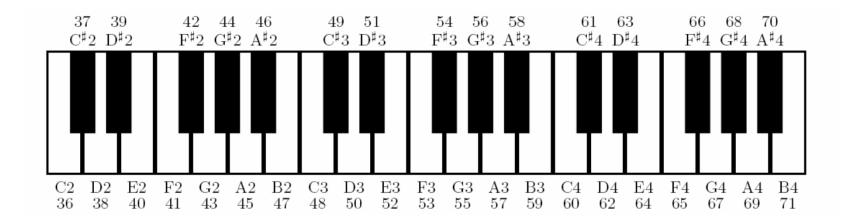

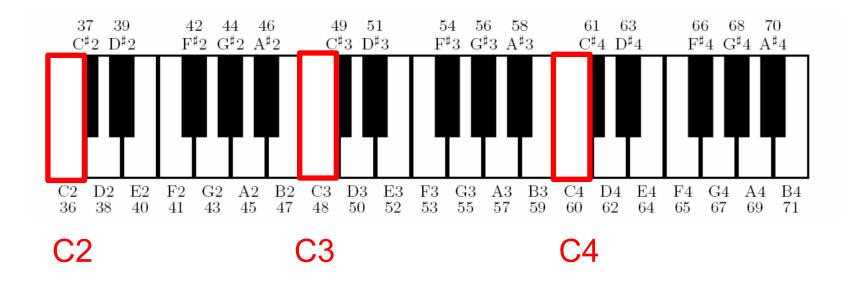

Chroma features

- Human perception of pitch is periodic in the sense that two pitches are perceived as similar in color if they differ by an octave.
- Seperation of pitch into two components: tone height (octave number) and chroma.
- Computation: pitch features → chroma features
 Add up all pitches belonging to the same class
- Result: 12-dimensional chroma vector.

Chroma features

NIIN,

Chroma features

Chroma features

- Sequence of chroma vectors correlates to the harmonic progression
- Normalization x → x/||x|| makes features invariant to changes in dynamics
- Further denoising and smoothing
- Taking logarithm before adding up pitch coefficients accounts for logarithmic sensation of intensity

Audio Features Logarithmic compression

For a positive constant $\gamma \in \mathbb{R}_{>0}$ the logarithmic compression

$$\Gamma_{\gamma}:\mathbb{R}_{>0}\to\mathbb{R}_{>0}$$

is defined by

 $\Gamma_{\gamma}(v) := \log(1 + \gamma \cdot v)$

A value $v \in \mathbb{R}_{>0}$ is replaced by a compressed value $\Gamma_{\gamma}(v)$

Audio Features Logarithmic compression

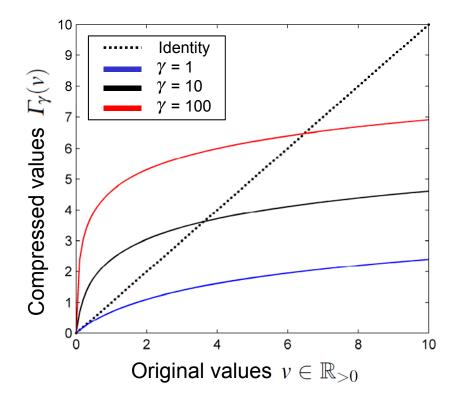

For a positive constant $\gamma \in \mathbb{R}_{>0}$ the logarithmic compression

$$\Gamma_{\gamma}:\mathbb{R}_{>0}\to\mathbb{R}_{>0}$$

is defined by

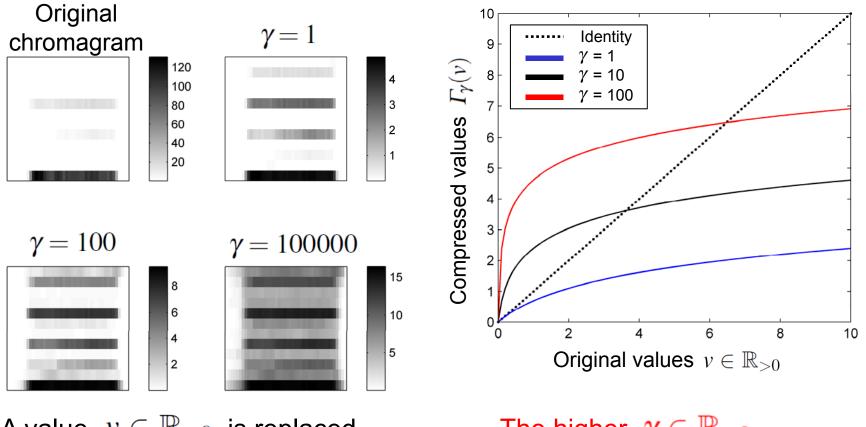

$$\Gamma_{\gamma}(v) := \log(1 + \gamma \cdot v)$$

A value $v \in \mathbb{R}_{>0}$ is replaced by a compressed value $\ \Gamma_{\gamma}(v)$

The higher $\gamma \in \mathbb{R}_{>0}$ the stronger the compression

Logarithmic compression

A value $v \in \mathbb{R}_{>0}$ is replaced by a compressed value $\Gamma_{\gamma}(v)$ The higher $\gamma \in \mathbb{R}_{>0}$ the stronger the compression

Audio Features Normalization

Replace a vector by the normalized vector x/||x||using a suitable norm $\|\cdot\|$

Example: Chroma vector $x \in \mathbb{R}^{12}$ Euclidean norm

$$||x|| := \left(\sum_{i=0}^{11} |x(i)|^2\right)^{1/2}$$
